

Regular Expressions

https://www.tutorialspoint.com/python/python_reg_expressions.htm

<https://www.youtube.com/watch?v=paOPoZyjdG>

- A regular expression is a string containing a series of characters, some of which may have a special meaning. For example, the three characters `.`, `|`, and `*` have the special meanings concatenate, or, and Kleene star respectively. For example, the regular expression `0.1` means a 0 followed by a 1, `0|1` means a 0 or a 1, and `1*` means any number of 1's.
- When you want to perform string matching operations that are more complex than the operations, you use regular expressions.
- A regular expression is a special sequence of characters that helps you match or find other strings or sets of strings, using a specialized syntax held in a pattern. Regular expressions are widely used in UNIX world.
- The module `re` provides full support for Perl-like regular expressions in Python. The `re` module raises the exception `re.error` if an error occurs while compiling or using a regular expression.

Regular Expression - Examples

Describe the following sets as Regular Expressions

- 1) $\{0,1,2\}$ $0 \text{ or } 1 \text{ or } 2$
 $R = 0 + 1 + 2$
- 2) $\{\wedge, ab\}$
 $R = \wedge ab$
- 3) $\{abb, a, b, bba\}$ $abb \text{ or } a \text{ or } b \text{ or } bba$
 $R = abb + a + b + bba$
- 4) $\{\wedge, 0, 00, 000, \dots\}$
- 5) $\{1, 11, 111, 1111, \dots\}$

Shunting Yard Algorithm

https://rosettacode.org/wiki/Parsing/Shunting-yard_algorithm

<https://web.microsoftstream.com/video/a29536d4-e975-4172-a470-40b4fe28866e>

- Edsger Dijkstra developed his "Shunting Yard" algorithm to convert an infix expression into a postfix expression. It uses a stack; but in this case, the stack is used to hold operators rather than numbers. The purpose of the stack is to reverse the order of the operators in the expression. It also serves as a storage structure, since no operator can be printed until both of its operands have appeared.

Shunting Yard Algorithm done by hand

● Shunting Yard Algorithm ●

● takes regular expressions from infix notation to postfix notation
concatenates operations

infix $\left\{ \begin{array}{l} a.b = a \text{ followed by } b \\ a|b = a \text{ or } b \\ a^+ = \text{an number of } a\text{'s (includes } \emptyset \end{array} \right.$

Post fix $\left\{ \begin{array}{l} ab. = a \text{ followed by } b \\ a|b = \text{an } a \text{ or } b \\ a^+ = \text{any no of } a\text{'s (includes } \emptyset \end{array} \right.$

SYA = convert infix notation into postfix

Eg $(a|b).(a^+|b^+)$ output
(post fix)
 $ab|a^+b^+|.$

String - abbb

$(a|b).(a^+|b^+)$ b a b^+ $a^+|b^+$
 $\underline{a} \Rightarrow \underline{a|b}$ $\underline{a|b}$ $\underline{a|b}$

$a|b.c = ? (a|b).c$ \times
 $= ? a|(b.c)$ \checkmark

Stack

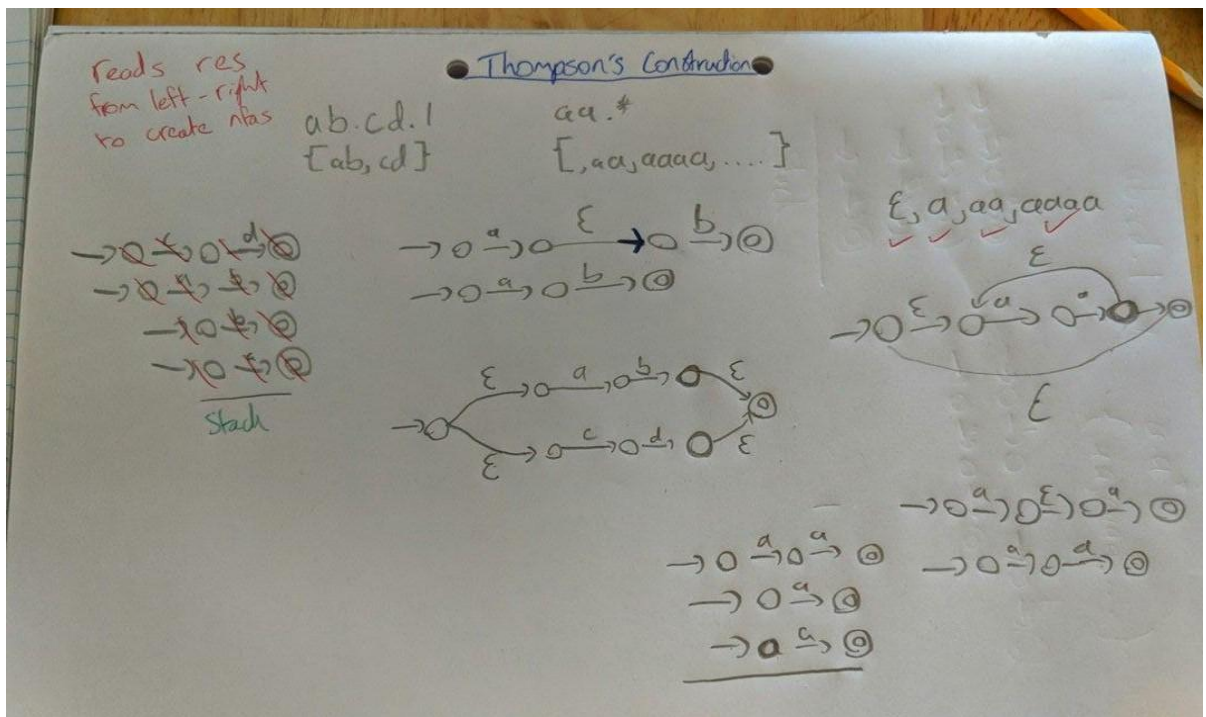

Thompson's Construction

https://en.wikipedia.org/wiki/Thompson%27s_construction

<https://web.microsoftstream.com/video/29de6c7c-9379-46d3-99e8-8a3dbafe391f>

- In computer science, Thompson's construction algorithm, also called the McNaughton-Yamada-Thompson algorithm, is a method of transforming a regular expression into an equivalent nondeterministic finite automaton (NFA). This NFA can be used to match strings against the regular expression. This algorithm is credited to Ken Thompson.
- Regular expressions and nondeterministic finite automata are two representations of formal languages. For instance, text processing utilities use regular expressions to describe advanced search patterns, but NFAs are better suited for execution on a computer. Hence, this algorithm is of practical interest, since it can compile regular expressions into NFAs. From a theoretical point of view, this algorithm is a part of the proof that they both accept exactly the same languages, that is, the regular languages.
